A chapter describes the alkylation of chiral hydrazones, a process that yields chiral-substituted aldehydes and ketones. Other chapters explore a variety of cyclization processes that form carbon-carbon and carbon-heteroatom bonds. The last chapters deal with the asymmetric cycloadditions and sigma-tropic rearrangements.

Alternative Title: stereoselective synthesis. Asymmetric synthesis, any chemical reaction that affects the structural symmetry in the molecules of a compound, converting the compound into unequal proportions of compounds that differ in the dissymmetry of their structures at the affected centre. Such reactions usually involve organic compounds in which the symmetrical structural feature is a carbon atom bonded to four other atoms or groups of atoms, of which two are alike; in the asymmetric ...

Chiral catalysts can be applied in asymmetric synthesis such as alkylation, Diels-Alder reaction, asym-metric reduction, hydroformylation, epoxylation, and dihydroxylation. The relationship between the chiral catalyst and the reaction system is just like the relationship between a lock and a key, which is highly selective.

Combination of Chiral Carbon Electrophiles with Carbon Nucleophiles Asymmetric nucleophilic catalysts can be used to generate chiral electrophiles. The union of these with prochiral carbon nucleophiles represents a promising catalytic approach to the synthesis of all-carbon quaternary stereocenters (Scheme 9).

Asymmetric Synthesis. If one could prepare 2-hydroxypropanenitrile from ethanal and hydrogen cyanide in the absence of any chiral reagent and produce an excess of one enantiomer over the other, this would constitute an absolute asymmetric synthesis - that is, creation of preferential chirality (optical activity) in a symmetrical environment from symmetrical reagents:

A chiral molecule or ion typically contains a chiral center or stereocenter. [dubious – discuss] When that center coincides with an atom, the substance is said to have point chirality. In chiral organic compounds, a stereocenter is often an asymmetric carbon. Multiple stereocenters may give rise to additional stereoisomers.

Asymmetric catalysis for chiral compound synthesis is a rapidly growing field in modern organic chemistry and provides enantioselective materials to meet the demands of various fields. However, the construction of all-carbon quaternary stereocenters poses a distinct challenge in organic synthesis. The development of catalytic asymmetric conjugate additions that require only a catalytic amount of a transition metal with a chiral ligand or organocatalyst has provided an efficient approach to ...
